Artificial Intelligence And Machine Learning Laboratory Manual

(18CSL76)

Program-1

Implement A* Search Algorithm

Algorithm:

1. Place the starting node list in “OPEN” list.
2. Check if the OPEN list is empty or not

   If list is empty then, return

   failure and stop
3. Select the node from “OPEN” set which has the smallest value of evaluation f.

   If node n is goal node then,

   Return success and stop
4. Expand node n and generate all of its successors and put n to the CLOSED list

- For each successor ‘n’ check whether its already there in OPEN and CLOSED list.
- If not compute f value and place into OPEN

Else if node n is already there in OPEN and CLOSE then it should be attached to back pointer which should reflect lowest g(n) value.

5. Return Step 2.

Program:

```
#!/usr/bin/env python
#coding utf-8
#ln[1]:

def aStarAlgo(start_node,stop_node):
    open_set=set(start_node
    ) closed_set=set() g={}
```

```
parents={} g[start_node]=0
parents[start_node]=start_nod
e while len(open_set)>0:
n=None for v in open_set:
        if n==None or g[v]+heuristic(v)<g[n]+heuristic(n):
            n=v
    if n==stop_node or Graph_nodes[n]==None:
        pass
    else:
        for(m,weight) in get_neighbors(n):
            if m not in open_set and m not in closed_set:
                open_set.add(m) parents[m]=n
            g[m]=g[n]+weight else:
                if g[m]>g[n]+weight:
                    g[m]=g[n]+weight
                    parents[m]=n if m in
                    closed_set:
                    closed_set.remove(m)
                    open_set.add(m)
    if n==None:
        print("path does not exist")
        return None
    if n==stop_node:
        path=[] while
        parents[n]!=n:
        path.append(n)
        n=parents[n]

        path.append(start_node)
        path.reverse() print('path
```

```
            found:{}'.format(path)) return
            path
        open_set.remove(n)
        closed_set.add(n)
    print("path doesnot exist")
    return None
def get_neighbors(v):
    if v in Graph_nodes:
        return Graph_nodes[v] else:
        return None
def heuristic(n):
    H_dist={
        'S':7,
        'A':6,
        'B':2,
        'C':1,
        'D':0

    } return
    H_dist[n]

Graph_nodes={
    'S':[('A',1),('B',4)],
    'A':[('B',2),('C',5),('D',12)],
    'B':[('C',2)],
    'C':[('D',3)],
}
aStarAlgo('S','D')
```

Output:

path found:['S', 'A', 'B', 'C', 'D']

['S', 'A', 'B', 'C', 'D']

Program 2 Implement

AO* Algorithm

Algorithm:

1. Let G be a graph with only starting node INIT.
2. Repeat the following until INIT is labeled as SOLVED or h(INIT)>FUTILITY.

- Select an unexpanded node from the most promising path from INIT (call it NODE).
- Generate SUCCESSORS of NODE.

  If ther are none,

  Set h(NODE)=FUTILITY(i.e NODE is unsolvable)

  Otherwise,

  For each SUCCESSORS that is not an ancestor of NODE

  Do the following:

  1. Add SUCCESSOR toG.
  2. If SUCCESSOR is a terminal node,

     label it SOLVED and set h(SUCCESSOR)=0
  3. If SUCCESSOR is not a terminal node,

     Compute its h value
- Propagate the newly discovered information up the graph by doing the following:

  1. Let S be set of SOLVED node or nodes whose h values have been changed and need to have values propagated back to their parents.
  2. Initialize S to node, until S is empty.
  3. Repeat the following:

     Remove a node from S and call it CURRENT.

Program:

```
class Graph:
    def __init__(self, graph, heuristicNodeList, startNode):
        self.graph = graph
        self.H=heuristicNodeList
        self.start=startNode
        self.parent={} self.status={}
        self.solutionGraph={}

    def applyAOStar(self): # starts a recursive AO* algorithm self.aoStar(self.start,
        False)

Program 3

For a given set of training data examples stored in a .CSV file, implement and demonstrate the Candidate-Elimination algorithm to output a description of the set of all hypotheses consistent with the training examples.

Algorithm:

1. Initialize G to the set of normally general hypothesis in H.
2. Initialize S to the set of maximally specific hypothesis in H.
3. For each training example d, do:
    a. If d is positive example
        - Remove from G any hypothesis h inconsistent with d
        - For each hypothesis s in S not consistent with d:
            - Remove s from S
            - Add to S all minimal generalizations of S consistent with d & having a generalization in G
            - Remove from S any hypothesis with a more specific h i n S
    b. If d is negative example
        - Remove from S any hypothesis h inconsistent with d
        - For each hypothesis g in G not consistent with d:
            - Remove g from G
            - Add to G all minimal specializations of g consistent with d &having a specialization in S
            - Remove from G any hypothesis having a more general hypothesis in G

Program 4

Write a program to demonstrate the working of the decision tree based ID3 algorithm. Use an appropriate data set for building the decision tree and apply this knowledge to classify a new sample.

Algorithm:

ID3(Examples, Target_attribute, Attributes)

Examples are the training examples.
Target_attribute is the attribute whose value is to be predicted by the tree.
Attributes is a list of other attributes that may be tested by the learned decision tree.
Returns a decision tree that correctly classifies the given Examples.

1.Create a Root node for the tree
2.If all Examples are positive,
Return the single-node tree Root,
with label = +
3.If all Examples are negative,
Return the single-node tree Root,
with label = -
4.If Attributes is empty,
Return the single-node tree Root,
withlabel=mostcommonvalueofTarget_attributein
Examples

Otherwise Begin,

- A ← the attribute from Attributes that best classifies Examples
- The decision attribute for Root ← A
- For each possible value, vi, of A,
  - Add a new tree branch below Root, corresponding to the test A = vi
  - Let Examples vi, be the subset of Examples that have value vi for A
    - If Examples vi , is empty

Then below this new branch add a leaf node with
label = most common value of Target_attribute in Examples
else
below this new branch add the subtree
ID3(Examples vi,Targe_tattribute,Attribute – {A}))

5.End
6.Return Root

Output:

The decision tree for the dataset using ID3 algorithm is

```
overcast yes
sunny

normal yes
high no
   rain

weak yes
strong
    no
The test instance xtest
The predicted labe1 no
The test instance xtest
The predicted labe1 yes
```

Program 5

Build a Artificial Neural Network by implementing the Backpropagation algorithm and test the same using appropriate data sets.

Algorithm:

BACKPROPAGATION (*training_example*, η, n_{in}, n_{out}, n_{hidden})

Each training example is a pair of the form $(\vec{x}, \vec{t})$, *where* $(\vec{x})$ *is the vector of network input values,* $(\vec{t})$ *and is the vector of target network output values.*
η *is the learning rate (e.g., .05).* n_i *is the number of network inputs,* n_{hidden} *the number of units in the hidden layer, and* n_{out} *the number of output units.*
The input from unit i into unit j is denoted x_{ji}, *and the weight from unit i to unit j is denoted* w_{ji}

- Create a feed-forward network with n_i inputs, n_{hidden} hidden units, and n_{out} output units.
- Initialize all network weights to small random numbers
- Until the termination condition is met, Do
    - For each $(\vec{x}, \vec{t})$, in training examples, Do

      Propagate the input forward through the network:
      1. Input the instance $\vec{x}$, to the network and compute the output o_u of every unit u in the network.

Propagate the errors backward through the network:

2. For each network output unit k, calculate its error term δ_k

$$\delta_k \leftarrow o_k(1 - o_k)(t_k - o_k)$$

3. For each hidden unit h, calculate its error term δ_h

$$\delta_h \leftarrow o_h(1 - o_h) \sum_{k \in outputs} w_{h,k}\delta_k$$

4. Update each network weight w_{ji}

$$w_{ji} \leftarrow w_{ji} + \Delta w_{ji}$$

Where

$$\Delta w_{ji} = \eta \delta_j x_{i,j}$$

Program:

```
import numpy as np
X=np.array(([2,9],[1,5],[3,6]),dtype=float)
y=np.array(([92],[86],[89]),dtype=float)

x=x/np.amax(X,axis=0)
y=y/100
```

```
def sigmoid(x): return
    1/(1+np.exp(-x))

def sigmoid_grad(x):

    Eo=y-output
    outgrad=sigmoid_grad(output)
    d_output=Eo*outgrad
    Eh=d_output.dot(wout.T)
    hiddengrad=sigmoid_grad(h_act)
    d_hidden=Eh*hiddengrad
    wout+=h_act.T.dot(d_output)*eta
    why=X.T.dot(d_hidden)*eta
print("Normalized input:\n"+str(X))
print("Actual output:\n"+str(y))
print("Predicted Output:\n",output)
```

Output:

```
Normalized input:
[[2. 9.]
[1. 5.]
[3. 6.]]
Actual output:
```

[[0.92]

[0.86]

[0.89]]

Predicted Output:

[[0.89224518]

[0.88542877]

[0.89224316]]

Program 6

Write a program to implement the navier Bayesian classifier for a sample training data set stored as a .csv file. Compute the accuracy of the classifier,considering few test data sets.

Explanation:

Bayes' Theorem is stated as:

$$P(h|D) = \frac{P(D|h)P(h)}{P(D)}$$

Where,

P(h|D) is the probability of hypothesis h given the data D. This is called the **posterior probability**.

P(D|h) is the probability of data d given that the hypothesis h was true.

P(h) is the probability of hypothesis h being true. This is called the **prior probability of h.**
P(D) is the probability of the data. This is called the **prior probability of D**

After calculating the posterior probability for a number of different hypotheses h, and is interested in finding the most probable hypothesis h ∈ H given the observed data D. Any such maximally probable hypothesis is called a ***maximum a posteriori (MAP) hypothesis***.

Bayes theorem to calculate the posterior probability of each candidate hypothesis is ***hMAP*** is a MAP hypothesis provided.

$$h_{MAP} = \arg\max_{h \in H} P(h|D)$$

$$= \arg\max_{h \in H} \frac{P(D|h)P(h)}{P(D)}$$

$$= \arg\max_{h \in H} P(D|h)P(h)$$

(Ignoring P(D) since it is a constant)

Gaussian Naive Bayes

A Gaussian Naive Bayes algorithm is a special type of Naïve Bayes algorithm. It's specifically used when the features have continuous values. It's also assumed that all the features are following a Gaussian distribution i.e., normal distribution

Representation for Gaussian Naive Bayes

We calculate the probabilities for input values for each class using a frequency. With realvalued inputs, we can calculate the mean and standard deviation of input values (x) for each class to summarize the distribution.

This means that in addition to the probabilities for each class, we must also store the mean and standard deviations for each input variable for each class.

Gaussian Naive Bayes Model from Data

The probability density function for the normal distribution is defined by two parameters (mean and standard deviation) and calculating the mean and standard deviation values of each input variable (x) for each class value. naviedata.csv:

$$\mu = \frac{1}{n}\sum_{i=1}^{n} x_i$$ Mean

$$\sigma = \left[\frac{1}{n-1}\sum_{i=1}^{n}(x_i - \mu)^2\right]^{0.5}$$ Standard deviation

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$ Normal distribution

Split 768 rows into train=514 and test=254 rows

Accuracy of the classifier is : 73.62204724409449%

Program 7

Apply EM algorithm to cluster a set of data stored in a .CSV file. Use the same data set for clustering using K-Means algorithm. Compare the results of these two algorithms and comment on the quality of clustering. You can add Java/Python ML Library classes/API in the program

Program:

```
import matplotlib.pyplot as plt from
sklearn import datasets from
sklearn.cluster import KMeans
import sklearn.metrics as sm import
pandas as pd import numpy as np

iris=datasets.load_iris()
X=pd.DataFrame(iris.data)
X.columns=['Sepal_Length','Sepal_Width','Petal_Length','Petal_Width']
y=pd.DataFrame(iris.target)
y.columns=['Targets']
model=KMeans(n_clusters=3)
model.fit(X)
plt.figure(figsize=(14,7))
colormap=np.array(['red','lime','black'])
plt.subplot(1,3,1)
plt.scatter(X.Petal_Length,X.Petal_Width,c=colormap[y.Targets],s=40)
plt.title('Real Clasification') plt.xlabel('Petal Length') plt.ylabel('Petal
Width')

plt.subplot(1,3,2)
plt.scatter(X.Petal_Length,X.Petal_Width,c=colormap[model.labels_],s=40)
plt.title('K Mean Classification') plt.xlabel('Petal Length') plt.ylabel('Petal
Width')
```

```
print('The accuracy score of K-Mean:',sm.accuracy_score(y,model.labels_))
print('The Confusion matrix of K-Mean:',sm.confusion_matrix(y,model.labels_))

from sklearn import preprocessing
scaler=preprocessing.StandardScaler()
scaler.fit(X) xsa=scaler.transform(X)
xs=pd.DataFrame(xsa,columns=X.columns)

from sklearn.mixture import GaussianMixture
gmm=GaussianMixture(n_components=3)
gmm.fit(xs)

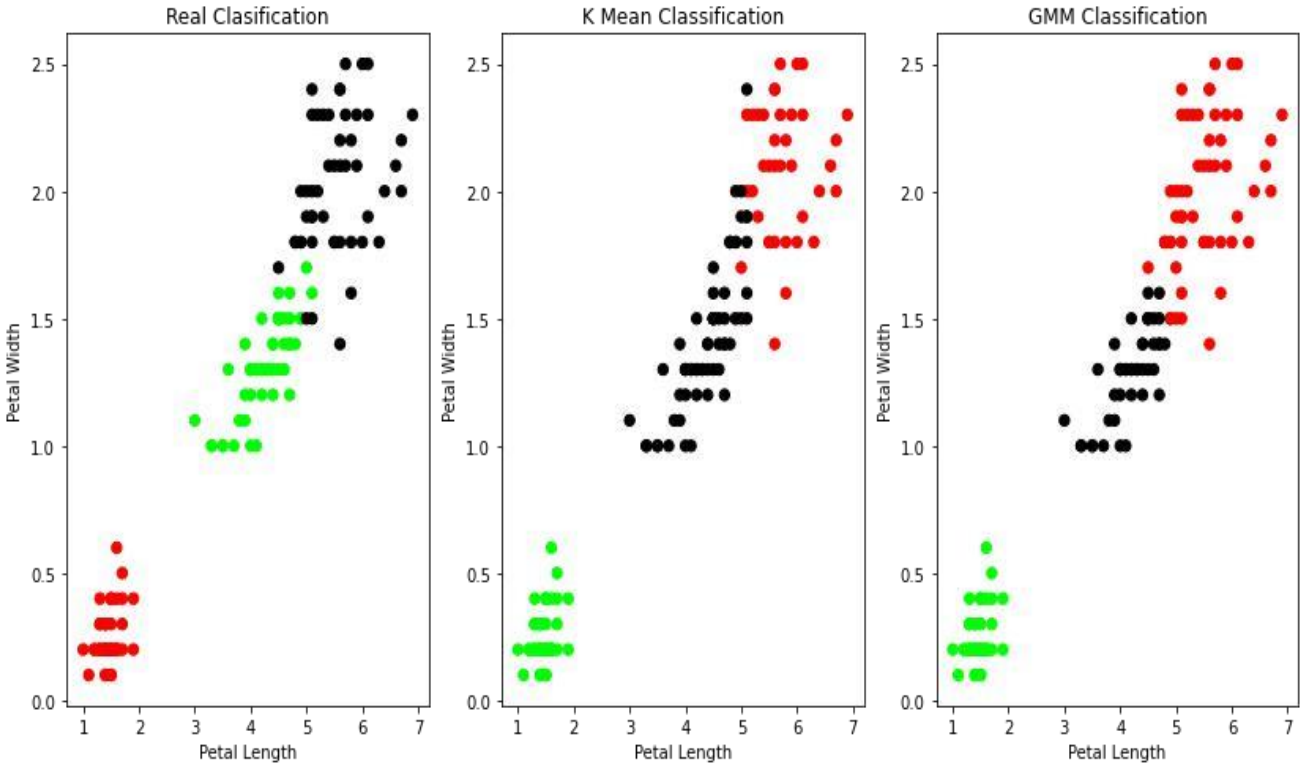
y_gmm=gmm.predict(xs)

plt.subplot(1,3,3)
plt.scatter(X.Petal_Length,X.Petal_Width,c=colormap[y_gmm],s=40)
plt.title('GMM Classification') plt.xlabel('Petal Length')
plt.ylabel('Petal Width')

print('The accuracy score of EM:',sm.accuracy_score(y,y_gmm)*100)
print('The confusion matrix of EM:',sm.confusion_matrix(y,y_gmm))
```

Output:

```
The accuracy score of K-Mean: 0.24
The Confusion matrix of K-Mean: [[ 0 50 0]
[2 0 48]
[36 0 14]]
The accuracy score of EM:30.0
The confusion matrix of EM: [[50 0 0]
[0 5 45]
[ 0 50 0]]
```



Program 8

Write a program to implement K-Nearest Neighbour algorithm to classify the iris data set.Print both correct and wrong predictions.Java/Python ML Library classes can be used for this problem.

Algorithm:

K-Nearest Neighbor Algorithm

Training algorithm:

- For each training example (x, f (x)), add the example to the list training examples

Classification algorithm:

- Given a query instance x_q to be classified,
  - Let $x_1 \ldots x_k$ denote the k instances from training examples that are nearest to x_q
  - Return

$$\hat{f}(x_q) \leftarrow \frac{\sum_{i=1}^{k} f(x_i)}{k}$$

  - Where, $f(x_i)$ function to calculate the mean value of the k nearest training examples.

Program:

```
from sklearn.datasets import load_iris
iris=load_iris()
print("Features Names:",iris.feature_names,"Iris Data:",iris.data,"Target
Names:",iris.target_names,"Target:",iris.target) from
sklearn.model_selection import train_test_split
X_train,X_test,y_train,y_test=train_test_split(iris.data,iris.target,test_size=.25)

from sklearn.neighbors import KNeighborsClassifier
clf=KNeighborsClassifier()
clf.fit(X_train,y_train)
print("Accuracy=",clf.score(X_test,y_test))
print("Predicted Data")
print(clf.predict(X_test))
prediction=clf.predict(X_test) print("Test
Data:") print(y_test) diff=prediction-y_test
print("Result is") print(diff)
print("Total no of samples misclassified=",sum(abs(diff)))
```

Output:

```

Program 9

Implement the non-parametric Locally Weighted Regression Algorithm in order to fit data points. Select appropriate data set for your experiment and draw graphs.

Algorithm:

Locally Weighted Regression Algorithm:

1. Read the Given data Sample to X and the curve (linear or non linear) to Y

2. Set the value for Smoothening parameter or Free parameter say τ

3. Set the bias /Point of interest set x0 which is a subset of X

4. Determine the weight matrix using :

$$w(x, x_o) = e^{-\frac{(x-x_o)^2}{2\tau^2}}$$

$$\hat{\beta}(x_o) = (X^T W X)^{-1} X^T W y$$

4. Determine the value of model term parameter β using:

5. Prediction = x0*β **CSV Files:**

tips.csv

total_bill	tip	sex	smoker	day	time	size
16.99	1.01	Female	No	Sun	Dinner	2
10.34	1.66	Male	No	Sun	Dinner	3
21.01	3.5	Male	No	Sun	Dinner	3
23.68	3.31	Male	No	Sun	Dinner	2
...	...	...	...	...	...	...

Program:

```
import matplotlib.pyplot as plt

import pandas as pd

import numpy as np
```

```
def kernel(point, xmat, k): m,n =
    np.shape(xmat) weights =
    np.mat(np.eye((m))) for j in
    range(m): diff = point - X[j]
        weights[j,j] = np.exp(diff*diff.T/(-2.0*k**2))
    return weights

def localWeight(point, xmat, ymat, k):
    wei = kernel(point,xmat,k) W =
    (X.T*(wei*X)).I*(X.T*(wei*ymat.T))
    return W

def localWeightRegression(xmat, ymat, k):
    m,n = np.shape(xmat) ypred = np.zeros(m) for i in
    range(m):
        ypred[i] = xmat[i]*localWeight(xmat[i],xmat,ymat,k)
    return ypred

# load data points data =
pd.read_csv('tips.csv') bill =
np.array(data.total_bill) tip =
np.array(data.tip) #preparing
and add 1 in bill mbill =
np.mat(bill) mtip =
np.mat(tip) m=
np.shape(mbill)[1]

one = np.mat(np.ones(m))
X = np.hstack((one.T,mbill.T))

#set k here
```

```
ypred = localWeightRegression(X,mtip,0.5)
SortIndex = X[:,1].argsort(0) xsort =
X[SortIndex][:,0] fig = plt.figure() ax =
fig.add_subplot(1,1,1) ax.scatter(bill,tip,
color='green')
ax.plot(xsort[:,1],ypred[SortIndex], color = 'red', linewidth=5)
plt.xlabel('Total bill') plt.ylabel('Tip')
plt.show();
```

Output:
